FROM: SFWMD Staff Environmental Advisory Team

DATE: September 30, 2026

SUBJECT: Weekly Environmental Conditions for Systems Operations

Summary

Weather Conditions and Forecast

From Wednesday into Thursday, a low will draw moisture across the SFWMD, particularly from late Wednesday into Thursday as a tropical wave moves through the western Caribbean Sea. Increased rainfall is favored across the interior and western part of the SFWMD from around Lake Okeechobee southward on Wednesday, while an increase in shower and thunderstorm activity is also possible along the Lower and Middle East Coast. Most indications are that rainfall will increase further on Thursday, with nearly widespread activity possible south of Lake Okeechobee following overnight and morning rainfall along and near the east coast. This activity should then spread into the interior and western part of the SFWMD during the afternoon. On Friday, widespread rainfall along and near the east coast during the morning following overnight activity is expected. By afternoon, rainfall should spread into the interior and particularly the northwestern half of the SFWMD; Lake Okeechobee westward should experience a good coverage of rainfall. Over the weekend, moisture levels, which are likely to remain rather high on Saturday, will begin to decrease on Sunday. Model solutions differ, however, on how effectively a relatively drier air mass arriving from the east will be able to spread into the SFWMD. Consequently, greater total daily SFWMD rainfall is likely on Saturday than Sunday, with both days favoring the interior and western portions of the area, particularly from Lake Okeechobee westward. By Monday, the areas of greatest rainfall will shift toward the central interior and away from the far west with moisture levels rebounding north of the Lake in response to moisture pooling ahead of a cold front settling into north Florida. For the week ending Monday morning, total SFWMD rainfall is forecast to be near the long-term average, with the heaviest weekly rainfall likely south of Lake Okeechobee. Looking farther ahead, there are strong indications that rainfall during the week-2 period of October 7–13 could be much above the long-term average. The potential for substantially enhanced rainfall during week 2 is associated not only with the possibility of a stalled frontal boundary over or north of the SFWMD but also with the possible development of a tropical or hybrid cyclone over the Gulf of Mexico or northwestern Caribbean Sea. Model guidance indicates a median week-2 forecast of roughly 2.3 inches of total rainfall across the SFWMD while the upper quartile of model solutions is around 3.4 inches.

Kissimmee

In the last week, releases were made from East Lake Toho and Lake Toho to lower stage back to the regulation schedule. Releases from Lakes Kissimmee-Cypress-Hatchineha followed the Headwaters Revitalization Schedule Increment 1 Temporary Deviation Discharge Plan. Weekly average discharge on September 27, 2026, was 1,400 cfs at both S-65 and S-65A. Mean weekly water depth on the Kissimmee River floodplain increased by 0.12 feet to 0.50 feet. The weekly average concentration of dissolved oxygen in the Kissimmee River decreased from 3.0 mg/L the previous week to 2.2 mg/L, which is above both the potentially lethal level of 1.0 mg/L and the stressful level of 2.0 mg/L for Florida bass and other species.

Lake Okeechobee

Lake Okeechobee stage was 10.51 feet NAVD88 (11.82 ft NGVD29) on September 27, 2026, which was 0.20 feet higher than the previous week and 0.94 feet higher than a month ago. The Lake remains in the water shortage management band. Average daily inflows (excluding rainfall) increased from 4,560 cfs the previous week to 5,560 cfs. Average daily outflows (excluding evapotranspiration) were 0 cfs for the fourth consecutive week. The September 27, 2026, satellite image from NOAA's Harmful Algal Bloom Monitoring System suggests moderate cyanobacteria potential across the western side of the Lake.

Estuaries

Total inflow to the St. Lucie Estuary averaged 2,051 cfs over the past week with no flow coming from Lake Okeechobee. Mean surface salinities decreased at the A1A Bridge site and remained steady at HR1 and US1 Bridge Sites. Salinity in the middle estuary was in the optimal range (10-25) for adult eastern oysters.

Total inflow to the Caloosahatchee River Estuary averaged 5,042 cfs over the past week with no flow coming from Lake Okeechobee. Over the past week, surface salinities decreased at Sanibel, remained steady at S-79 and Val I-75, and increased at the remaining sites in the estuary. Salinities were in the optimal range (0-10) for tape grass in the upper estuary. Salinities were in the lower stressed range (5-9) for adult oysters at Cape Coral, in the optimal range (10-25) at Shell Point, and in the upper stressed range (>25) at Sanibel.

Stormwater Treatment Areas

For the week ending September 27, 2026, no Lake Okeechobee water was delivered to the FEBs/STAs. The total amount of Lake releases sent to the FEBs/STAs in WY2027 is approximately 9,500 acre-feet. The total amount of inflows to the STAs in WY2027 is approximately 384,000 acre-feet. Most online STA treatment cells are above target stage. STA-1E Central Flow-way is offline for post-construction vegetation grow-in. STA-1W Eastern Flow-way is offline for vegetation management activities. Operational restrictions are in effect in STA-1E Eastern and Western Flow-way, STA-2 Flow-ways 1 through 4, STA-3/4 Eastern Flow-way and STA-5/6 Flow-ways 4 and 5 for vegetation management activities. This week, there is no lake release capacity in the STAs.

Everglades

Rainfall throughout the Everglades Protection Area (EPA) was above average for most of last week, falling to below average toward the end of the week. Average total rainfall across all basins was 1.11 inches. In correspondence with rainfall, ascensions in stage occurred across the EPA. WCA-1 and 2A are now at the 70th-90th percentiles. Water depths across WCA-3A continue to move towards the 20-year average but remain very shallow for this time of year. Most of the central Everglades and Everglades National Park remain below the 20th percentile. These dry conditions and stage deficits particularly in WCA-3 can have ecological consequences system wide, including reduced prey production, increased risk of damaging wildfires, enhanced peat oxidation, and potential ridge and slough degradation as the dry season approaches. Taylor Slough water levels exhibited a slight decrease but remain above the recent seasonal average by 1.2 inches. Florida Bay had a slight increase in salinity last week and remains well above the recent seasonal average bay-wide. The eastern region is now just below the hypersalinity threshold, while the central and western regions remain above it. Many areas of Florida Bay are currently experiencing record-high salinities for this time of year, driven by reduced freshwater inputs following below-normal rainfall throughout the wet season.

Supporting Information

Kissimmee Basin

Upper Kissimmee

On September 27, 2026, mean daily lake stages were 56.0 feet NAVD88 (0.1 feet above schedule) in East Lake Toho, 53.0 feet NAVD88 (0.1 feet above schedule) in Lake Toho, and 49.5 feet NAVD88 (1.3 feet below the Increment 1 Temporary Deviation schedule) in Lakes Kissimmee-Cypress-Hatchineha (KCH) (**Table KB-1, Figures KB-1-3**).

Lower Kissimmee

For the week ending September 27, 2026, mean weekly discharge was 1,400 cfs at both S-65 and S-65A. Mean weekly discharge from the Kissimmee River was 1,200 cfs at both S-65D and S-65E (**Table KB-2**). Mean weekly headwater stages were 45.3 feet NAVD88 at S-65A and 31.4 feet NAVD88 at S-65D. Mean weekly river channel stage increased by 1.5 feet to 34.7 feet NAVD88 (**Figure KB-4**). Mean weekly water depth on the Kissimmee River floodplain increased by 0.12 feet to 0.50 feet (**Table KB-2, Figure KB-5**). The weekly average concentration of dissolved oxygen in the Kissimmee River decreased from 3.0 mg/L the previous week to 2.2 mg/L (**Table KB-2, Figure KB-6**).

Water Management Recommendations

In KCH, follow the Headwaters Revitalization Schedule (HRS) Increment 1 Temporary Deviation Discharge Plan for S-65/S-65A (**Figure KB-7**). With KCH stage in Zone B2, target flows of 1,400 cfs; if stage increases into Zone B1, target flows between 1,400 and 3,000 cfs at S-65A using the Increment 1 Interpolation Tool to determine discharge relative to stage in KCH.

Table KB-1. Average discharge for the preceding seven days, Sunday's average daily stage and Sunday's average daily departure from Kissimmee Chain of Lakes (KCOL) flood regulation lines or temporary schedules. All data are provisional.

Water Body	Structure	Stage Monitoring Site	Weekly (7-Day) Average Discharge (cfs)	Sunday Lake Stage (feet NAVD88) ^a	Schedule Type ^b	Sunday Schedule Stage (feet NAVD88)	Sunday Departure from Regulation (feet)	
							9/27/26	9/20/26
Lakes Hart and Mary Jane	S-62	LKMJ	51	59.0	R	59.0	0.0	0.1

Report Date: 9/29/2026; data are through: 9/27/2026

Figure KB-6. Kissimmee River channel mean daily dissolved oxygen concentration (mg/L), S-65A discharge (cfs), temperature (°C) and rainfall (inches). Dissolved oxygen (DO) and temperature are mean daily values averaged for PC62, KRDR02, KRBN, PC33, PC11, PD62R, and PD42R with an average of five stations reporting this week. Rainfall values are daily totals for Kissimmee River (Pool BCD) AHED watershed.

SOUTH FLORIDA WATER MANAGEMENT DISTRICT

HRS Increment 1 Temporary Deviation Discharge Plan for S-65/S-65A

Discharge Guidance for Increment 1 Temporary Deviation Discharge Plan		
ZONE	S-65 RELEASES	S-65A TARGET FLOWS
ZONE A	Releases for Flood Risk Management up to maximum structure capacity as determined by downstream constraints with a firm capacity of 3,000 cfs.	
ZONE B1	1,400 cfs minimum ramp to 3,000 cfs at Zone A boundary	S-65A releases between 1,400 cfs and 3,000 cfs at Zone A boundary based on Table 1
ZONE B2	Releases as needed to target flows at S-65A	Target S-65A flows of 1,400 cfs to meet ecological needs
ZONE B3	Releases as needed to target flows at S-65A	S-65A flows between 300 cfs and 1,400 cfs
ZONE B4	Releases as needed to target flows at S-65A	Target S-65A flows of 300 cfs
ZONE B5	Releases as needed to target flows at S-65A	Target S-65A flows of 150 cfs
ZONE C	0 cfs	Flow as needed to maintain optimum S-65A headwater

Table KB-3. Maximum Rate of Change Limits for S-65A		
MAXIMUM Release Rate of Change Limits for S-65A. In general recommended rates of change will be slower than shown in this table.		
Q (cfs)	Maximum rate of INCREASE (cfs/day)	Maximum rate of DECREASE (cfs/day)
0-300	50	-50
301-650	75	-75
651-1400	150	-150
1401-3000	300	-600
>3000	1000	-2000

sfwmd.gov

Other Considerations

- When possible, limit lake ascension rate in the Jun 1 - Aug 15 window to 0.25 ft per 7 days in Lakes Kissimmee, Cypress, Hatchineha (S-65), East Toho (S-59) and Toho (S-61).
- If outlook is for extreme dry conditions meet with KB staff to discuss modifications to this plan.

Slide Revised 7/29/2024

Figure KB-7. Headwaters Revitalization Schedule (HRS) Increment 1 Temporary Deviation Discharge Plan for S-65/S-65A.

Lake Okeechobee

Lake Okeechobee stage was 10.51 feet NAVD88 (11.82 ft NGVD29) on September 27, 2026, which was 0.20 feet higher than the previous week and 0.94 feet higher than a month ago (**Figure LO-1**). Lake stage remains in the water shortage management band (1.12 feet below the upper limit, **Figure LO-2**) and is 1.08 feet below the ecological envelope (**Figure LO-3**). According to NEXRAD, 0.36 inches (approximately 13,500 acre-feet) of rain fell directly over the Lake during the previous week, and 1.02 inches (approximately 30,300 acre-feet) were lost to evapotranspiration.

Average daily inflows (excluding rainfall) increased from 4,560 cfs the previous week to 5,560 cfs. The largest inflows came from the Kissimmee River (1,190 cfs via S65E(X)), followed by and Fisheating Creek (730 cfs). There was also backflow from the C-44 Canal (640 cfs via S-308) and the L-8 Canal (640 cfs via S-271). Average daily outflows (excluding evapotranspiration) were 0 cfs for the fourth consecutive week. **Figures LO-4 and LO-5** show the combined average daily inflows and outflows for the Lake over the past eight weeks, and the average inflows and outflows last week, respectively.

In the most recent non-obscured satellite image from September 27, 2026, NOAA's Harmful Algal Bloom Monitoring System suggests moderate cyanobacteria potential across the western side of the Lake (**Figure LO-6**).

Note: All data presented in this report are provisional and are subject to change.

Figure LO-1. Lake Okeechobee water depth estimates based on South Florida Water Depth Assessment Tool (SFWDAT).

Figure LO-2. Recent Lake Okeechobee stages with projected stages based on a conditional position analysis.
 Note: stages are in NGVD29, approximate NAVD88 values are shown for reference.

Figure LO-3. The current and select prior year's annual lake stage hydrographs in comparison to the Lake Okeechobee ecological envelope (light grey).

Figure LO-4. Major inflows (orange) to and outflows east and west (blue) from Lake Okeechobee. Outflows south are shown in green. Flows into Lake Okeechobee from the L-8 canal through S-271 (formerly Culvert 10A) or from the C-44 canal through the S-308 are included as inflows. Conversely, flows from Lake Okeechobee into the L-8 or C-44 canals are included with outflows. Inflows are shown as positive values; outflows are negative. Outflows through the S-77 (Caloosahatchee) and S-308 (C-44 Canal) structures are based on downstream gauges to include flows to lock openings for navigation.

Figure LO-5. Inflows into Lake Okeechobee from Indian Prairie basins, Taylor Creek/Nubbin Slough, Kissimmee River and Fisheating Creek (currently no flow data available for FECR), and outflows to the west via S-77, to the east via S-308, to the south via S-351, S-352, S-354, and to southeast via S-271 (formerly Culvert 10A) for the week of September 21 - 27, 2026.

Figure LO-6. Cyanobacteria bloom index level on Lake Okeechobee, based on NOAA's harmful algal bloom monitoring system. Gray color indicates cloud cover. *Provisional NOAA image, subject to change*.

Estuaries

St. Lucie Estuary

Over the past week, mean total inflow to the St. Lucie Estuary was 2,051 cfs (**Figures ES-1 and ES-2**), and the previous 30-day mean inflow was 1,591 cfs. For comparison, the historical provisional mean inflows from contributing areas are shown in **Figure ES-2**.

Over the past week, surface salinities decreased at the A1A Bridge site and remained steady at HR1 and US1 Bridge sites (**Table ES-1 and Figure ES-3**). The seven-day moving average water column salinity at the US1 Bridge was 11.7. Salinity conditions in the middle estuary were estimated to be within the optimal range (10-25) for adult eastern oysters (**Figure ES-4**). The mean larval oyster recruitment rate reported by the Fish and Wildlife Research Institute (FWRI) for August was 1.6 spat/shell at Rio, which is a decrease from the previous month (**Figure ES-5**).

Caloosahatchee River Estuary

Over the past week, mean total inflow to the Caloosahatchee River Estuary was 5,042 cfs (**Figures ES-6 and ES-7**), and the previous 30-day mean inflow was 4,602 cfs. For comparison, the historical provisional mean inflows from the contributing areas are shown in **Figure ES-7**.

Over the past week, surface salinities remained steady at S-79 and Val I-75, increased at Ft. Myers, Cape Coral, and Shell Point, and decreased at Sanibel (**Table ES-2 and Figures ES-8 and ES-9**). The seven-day mean water column salinity was in the optimal range (0–10) for tape grass in the upper estuary. The seven-day mean salinity values were within the lower stressed range (5-9) for adult eastern oysters at Cape Coral, the optimal range (10-25) at Shell Point, and in the upper stressed range (>25) at Sanibel (**Figure ES-10**). The mean larval oyster recruitment rates reported by the FWRI in August were 3.4 spat/shell at Iona Cove and 9.6 spat/shell at Bird Island, which is no change at Iona Cove and an increase at Bird Island compared to the previous month (**Figures ES-11 and ES-12**).

Surface salinity at Val I-75 was forecast for the next two weeks using an autoregression model (Qiu and Wan, 2013¹) coupled with a linear reservoir model for the tidal basin. Model scenarios included pulse releases at S-79 ranging from 450 to 2,000 cfs, with estimated tidal basin inflows of 659 cfs. Model results from all scenarios predict daily salinity to be 0.5 or lower and the 30-day moving average surface salinity to be 0.3 at Val I-75 at the end of the two-week period (**Table ES-3 and Figure ES-13**). This keeps predicted salinities in the upper estuary within the optimal salinity range (0–10) for tape grass.

¹ Qiu, C., and Y. Wan. 2013. Time series modeling and prediction of salinity in the Caloosahatchee River Estuary. *Water Resources Research* 49:5804-5816.

Red Tide

The FWRI reported on September 25, 2026, that *Karenia brevis*, the Florida red tide dinoflagellate, was not observed above background concentrations in any samples collected within the District region.

Water Management Recommendations

Lake stage is in the Water Shortage Management Zone. Current climatological and hydrological conditions are normal. The LOSOM release guidance suggests no releases at S-79 to the Caloosahatchee River Estuary and no releases at S-80 to the St. Lucie Estuary.

Figure ES-1. Basins, water control structures and salinity monitoring sites in the St. Lucie Estuary.

Figure ES-2. Total daily inflows from Lake Okeechobee and runoff from the C-44, C-23, C-24, Ten Mile Creek, and Tidal Basins into the St. Lucie Estuary.

Table ES-1. Seven-day mean salinity at oyster monitoring sites in the St. Lucie Estuary. Current means are in bold font; previous week's means are in parentheses. The envelope reflects the optimum salinity range for adult eastern oysters (*Crassostrea virginica*) in the estuary. Data are provisional.

Sampling Site	Surface	Bottom	Optimum Envelope
HR1 (North Fork)	3.7 (3.7)	9.9 (11.4)	10.0 – 25.0
US1 Bridge	8.8 (8.8)	14.7 (12.6)	10.0 – 25.0
A1A Bridge	17.1 (17.6)	21.1 (22.9)	10.0 – 25.0

Figure ES-3. Mean daily salinity at the A1A, US1, and HR1 sites in the St. Lucie Estuary.

Figure ES-4. Seven-day moving average of the surface and bottom salinities at the US1 Bridge in the St. Lucie Estuary.

Figure ES-5. Mean oyster recruitment at the Rio oyster monitoring station and 14-day mean salinity at US1 Bridge.

Figure ES-6. Basins, water control structures, and salinity monitoring sites in the Caloosahatchee River Estuary.

Figure ES-7. Total daily inflows from Lake Okeechobee, and runoff from the C-43 and Tidal basins into the Caloosahatchee River Estuary.

Table ES-2. Seven-day mean salinity at six monitoring sites in the Caloosahatchee River Estuary. Current means are in bold font; previous week's means are in parentheses. The envelope in the upper estuary sites is for the protection of tape grass and the envelope in the lower estuary is the optimum salinity range for adult eastern oysters (*Crassostrea virginica*). Data are provisional.

Sampling Site	Surface	Bottom	Optimum Envelope
S-79 (Franklin Lock)	0.2 (0.2)	0.2 (0.2)	0.0 – 10.0
Val I-75	0.3 (0.3)	0.2 (0.2)	0.0 – 10.0
Fort Myers Yacht Basin	1.1 (0.7)	2.9 (1.7)	0.0 – 10.0
Cape Coral	6.1 (5.9)	8.4 (9.2)	10.0 – 25.0
Shell Point	21.8 (20.4)	25.1 (23.9)	10.0 – 25.0
Sanibel	27.2 (29.5)	35.0 (36.4)	10.0 – 25.0

Stormwater Treatment Areas

STA-1E: STA-1E Central Flow-way is offline for construction activities. An operational restriction is in place in the Western Flow-way for post-construction vegetation grow-in. Online treatment cells are above target stage. The 365-day PLRs for the Western and Eastern Flow-way are below 1.0 g/m²/year (**Figure S-2**).

STA-1W: STA-1W Eastern Flow-way is offline for vegetation management activities. Treatment cells are above target stage. Vegetation in the Western and Eastern Flow-ways is highly stressed. The 365-day PLRs for the Northern and Western Flow-ways are below 1.0 g/m²/year (**Figure S-2**).

STA-2: Treatment cells are above target stage. An operational restriction is in place in Flow-way 2 for vegetation management activities. The 365-day PLRs for all Flow-ways are below 1.0 g/m²/year (**Figure S-3**).

STA-3/4: An operational restriction is in place in the Eastern Flow-way for vegetation management activities. Treatment cells are above target stage. Vegetation in the Central Flow-way is highly stressed. The 365-day PLRs for the Eastern, Central, and Western Flow-ways are below 1.0 g/m²/year (**Figure S-3**).

STA-5/6: Treatment cells are above target stage. All treatment cells have highly stressed vegetation conditions. The 365-day PLRs for all Flow-ways are below 1.0 g/m²/year. (**Figure S-4**).

For definitions on STA operational language see glossary following figures.

Everglades Stormwater Treatment Areas - STAs

- Total WY2027 inflows to STAs (5/1/2026 to 9/27/2026): ~384,000 ac-ft
- Lake Okeechobee releases to FEBs/STAs
 - 9/21/2026 to 9/27/2026: 0 ac-ft
 - WY 2027: ~ 9,500 ac-ft
- Extensive vegetation management activities underway to address stressed and highly stressed vegetation in EAV cells
- All treatment cells are at or above target water depth

Estimated Inflow and Outflow Volumes

Sep. 21st, 2026 - Sep. 27th, 2026 *Includes preliminary data*

	Total Inflow (acre-feet)	Total Outflow (acre-feet)
STA-1E	9,600	10,000
STA-1W	16,000	23,000
STA-2	19,000	26,000
STA-3/4	31,000	30,000
STA-5/6	5,200	5,300

Water Depths (9/27/2026)

Includes preliminary data; Emergent Aquatic Vegetation (EAV); Submerged Aquatic Vegetation (SAV)

Basic Concepts and Definitions for STA Weekly Status Report

- **Inflow:** Sum of flow volume at all inflow structures to an STA.
- **Lake Inflow:** Portion of the STA total inflow volume that originates from Lake Okeechobee.
- **Outflow:** Sum of flow volume at outflow structures from an STA.
- **Total Phosphorus (TP):** Total mass of phosphorus in all its forms; including particulate, dissolved, etc.
- **Inflow Concentration:** TP concentration is the mass of TP in micrograms per liter of water, $\mu\text{g/L}$ or ppb. Inflow concentration refers to the flow-weighted mean TP from all inflow structures over a period of time.
- **Outflow Concentration:** The flow-weighted mean TP from all outflow structures over a period of time. The outflow concentration represents the reduction of inflow TP achieved by STA treatment of the inflow water.
- **WQBEL:** The STA outflow concentration that is required upon completion of the Restoration Strategies projects by December 2025. The outflow concentration shall not exceed 13 ppb as an annual flow weighted mean in more than 3 out of 5 water years on a rolling basis and shall not exceed 19 ppb as an annual flow weighted in any water year.
- **Flow-Way (FW):** One or more treatment cells connected in series. Cells typically have emergent aquatic vegetation (EAV) in the front portion of the flow-way followed by a mix of EAV and submerged aquatic vegetation (SAV)
- **Vegetation Status:** Healthy means the vegetation condition is good and will allow the STA to perform as designed. Stressed means the vegetation is showing signs of poor health, such as browning or areas of vegetation die-off, or the cell contains undesirable vegetation such as floating exotic vegetation requiring treatment. The TP reduction capability of the STA is affected when the vegetation condition is poor.
- **Phosphorus Loading Rate (PLR):** Mass of inflow TP in grams, divided by total treatment area of STA in square meters, per year. In general, a 365-day value of less than 1.0 is needed for an STA to perform optimally. A PLR of 2.0 is considered very high and a PLR of 3.0 is considered extremely high. The TP reduction capability of the STA is affected when the PLR is high, very high and extremely high.
- **Online:** Online status means the FW can receive and treat inflow.
- **Online with Restriction:** The FW can receive and treat inflow, but the amount of flow or water level may be limited temporarily. For example, a vegetation rehabilitation effort may require reduced flows through an area while the new plants are establishing, or nesting by protected species may require a certain water level not to be exceeded.
- **Offline:** The FW is unable to receive and treat inflow due to repairs, construction, or other prohibitive reasons.
- **Depth:** Difference between the average surface water level in a cell and the average ground elevation in that cell. Target depths, or depths between flow events, are between 1.25 ft to 1.5 ft. As depth approaches or drops below zero, an increasing percentage of the cell is considered dry and STA conditions deteriorate. An increase in depth above target depth is expected with increasing flow. However, as depth increases much above the target depth and is sustained over a period of time, it can be detrimental to vegetation health and overall STA treatment performance.
- **Note:** The data provided in this summary report were developed using a combination of provisional and quality-assured flow and water quality data. In some cases, best professional judgment was used to estimate missing data and revise questionable data. Values provided are not considered final but are appropriate for use in STA operational decision-making.

Everglades

Water Conservation Areas

Regulation Schedules

WCA-1: Stage rose quickly at the 1-8C gauge last week but remained below the A-1 regulation line by 0.13 feet on Sunday, September 28, 2026 (**Figure EV-1**).

WCA-2A: Water depth at the 2-17 gauge continued to increase last week, leveling off at the end of the week. Stage was above the regulation line on Sunday by 1.04 feet (**Figure EV-2**).

WCA-3A: The 3-gauge average stage remains well within Zone B, with a more gradual incline over the week than the northern basins. On Sunday, stages were 0.92 feet below the Zone A regulation line. Stage at Gauge 62 (NW corner) showed a slight decline toward the end of the week and remains below the Upper Schedule line by 0.43 feet on Sunday (**Figures EV-3 and EV-4**).

Water Depths

The SFWDAT model output for September 28, 2026, illustrates a significant increase in water depths across WCA-1 and WCA-2A compared to a month ago. Rapid ascensions in south central WCA-2A slowed with conditions now above the 75th percentile in the southcentral of that basin and close to the 75th percentile in the north. Water levels continued to increase in NE WCA-3A and are within the 10th percentile for that region. The central and southern regions of WCA-3A followed the same increasing trend, but water depths fall well below the 10th percentile. Water depths in WCA-3B are below the 20th percentile across most of that sub-basin. The Big Cypress basin is also showing a stable wetting trend, although there are issues with the model output in this region. In Everglades National Park (ENP) connectivity in both Taylor Slough (TS) and Shark River Slough (SRS) improved over the last month, with greater potential for connectivity in the west compared to last week. Water depths remain in the 10th – 30th percentile for this time of year across most the central Everglades Protection Area (EPA) impacting soil, flora, and fauna (**Figures EV-5 and EV-6**). Recurring below average water depths in the central Everglades are illustrating the system level importance of maintaining water in the sloughs and low-water refugia for wildlife and vegetation needs.

Taylor Slough and Florida Bay

Stage changes were variable across Taylor Slough over the past week, with an average decrease of 0.04 feet. Changes ranged from -0.23 feet at Taylor Slough Bridge (TSB) in the northern slough to +0.10 feet at EPSW in the C-111 area (**Figure EV-7 and Figure EV-8**). Taylor Slough water levels are above the recent average (WY1993-2016) for this time of year by 1.2 inches compared to before the Florida Bay Initiative (starting in 2017), a decrease of 1.3 inches relative to last week. Stages at Craighead Pond (CP) and TSB are below the estimated historical average by 0.74 and 1.33 feet, respectively.

Average salinity in Florida Bay was 39.1, an increase of 0.6 from last week. Salinity changes ranged from -2.9 at Duck Key (DK) in the eastern region to +9.6 at Joe Bay (JB)

in the eastern nearshore region (**Figure EV-7**). Salinity is above the estimated historical average and above the WY2001-2016 Interquartile Range (IQR) 75th percentile in all regions (**Figure EV-9**). Salinity in the eastern region is just below the hypersalinity threshold, while the central and western regions are above it. Bay-wide salinity remains above its recent average (WY1993-2016) for this time of year by 13.5, an increase of 0.2 from last week.

Salinity at the Taylor River (TR) station in the mangrove zone (tracked for the Florida Bay MFL) was 21.6, an increase of 5.3 from last week (**Figure EV-10**). The 365-day moving sum of flow from the five major creeks (McCormick Creek, Taylor River, Mud Creek, Trout Creek, West Highway Creek) was unable to be assessed due to missing data.

Average rainfall across Taylor Slough and Florida Bay was 0.82 inches over the past week, based on the 18 gauges used for this report. Rainfall ranged from 0.20 inches at Royal Palm Lake (RPL) in the northern slough to 2.27 inches at Trout Creek (TC) in the eastern nearshore region (**Figure EV-11**). Wind directions and speeds in Florida Bay ranged from 0.2 mph SW to 19.4 mph SE, both on September 23rd (**Figure EV-11**).

The Taylor River, Mud Creek, and West Highway Creek flow stations are currently offline until further notice, so data from all five major creeks are unable to be assessed. Based on the available data from Trout and McCormick Creeks, average daily flow totaled 117 acre-feet, with net positive flows for the week. Total daily creek flow ranged from -1,334 acre-feet on September 27th to 1,159 acre-feet on September 24th (**Figure EV-13**). Average daily flow from Alligator Creek was -23 acre-feet, with net negative flows for the week (**Figure EV-13**). High tides over the past week were likely a driver of negative creek flow, thus contributing to higher salinities.

Implications/considerations for water management

- Due to current low water conditions for this time of year that remain in the central Everglades, continued ascensions would help to protect the wetland ecology from damaging dry conditions during the wet season.
 - With continued drought conditions, conserving water within the WCAs, especially WCA-3A, will continue to be ecologically beneficial.
- A continued ascension but at a moderate rate in the northern basins to reach peak wet season water depths would be ecologically beneficial as conditions move into the dry season.
- Freshwater input into Taylor Slough and the C-111 basin could help moderate salinities and support recovery of estuarine conditions in Florida Bay.
 - Hypersaline conditions in the north-central region of Florida Bay tied with elevated temperatures could lead to seagrass die-off conditions if freshwater input does not continue to increase.
- Conserving water in the WCAs while providing freshwater input to the sloughs of ENP will require careful consideration of a balance between the upstream and downstream ecological needs of the system. Individual regional recommendations can be found in **Table EV-2**.

Table EV-1. Previous week's rainfall and water depth changes in Everglades basins.

Everglades Region		Rainfall (Inches)	Stage Change (feet)
WCA-1	0.84		+0.30
WCA-2A	0.93		+0.25
WCA-2B	0.98		+0.38
WCA-3A	1.06		+0.10
WCA-3B	1.95		+0.01
ENP	0.89		+0.05

Figure EV-3. WCA-3A stage hydrographs (three-gauge average, 3-69W) and regulation schedule.

Figure EV-4. WCA-3A stage hydrograph (Deer gauge; Site 62) and regulation schedule.

Figure EV-5. Everglades water depths from two months ago (left), one month ago (center) and present (right), based on SFWDAT.

Figure EV-6. Present water depths (September 28, 2026) compared to the day of year relative to average (percentile) over the previous 20 years. Yellow star indicates an error in the model.

Figure EV-7. Taylor Slough water depths and Florida Bay salinities with changes since a week ago.

Figure EV-8. Taylor Slough water depth time series for Taylor Slough Bridge (TSB; northern slough) and Craighead Pond (CP; southern slough).

Figure EV-9. Eastern (top panel), Central (middle panel) and Western (bottom panel) Florida Bay daily average salinities with WY2001-2016 interquartile (25-75 percentile) ranges (IQR) and estimated historical daily average salinities. The hypersalinity threshold indicates the level at which salinities start to become harmful to seagrass.

Figure EV-10. Daily average salinity at Taylor River (TR) tracked for the Florida Bay MFL criteria. The 365-day total creek flow MFL metric is not currently available due to missing creek flow data.

Figure EV-11. Daily average rain across Taylor Slough and Florida Bay, along with hourly average wind speed and direction (measured at Long Key) in Florida Bay over the past four weeks.

Figure EV-12. Top: daily average creek flow summed between the five major creeks with estimated historical daily flow over the past four weeks (**note:** data from Taylor River, Mud Creek and West Highway Creek are currently unavailable since May 28th, 2026). Bottom: Daily average Alligator Creek flow data.

Table EV-2. Weekly water depth changes and water management recommendations

SFWMD Everglades Ecological Recommendations, September 28th, 2026 (red is new)			
	Weekly change	Recommendation	Reasons
WCA-1	Stage increased by 0.30 feet	An ascension of no faster than 0.25 feet per week	Conserve water, maintain within basin and downstream habitat and wildlife. Maintain maintenance access for vegetation management.
WCA-2A	Stage increased by 0.25 feet	An ascension of no faster than 0.25 feet per week	Conserve water, maintain within basin (north versus south) and downstream habitat and wildlife.
WCA-2B	Stage increased by 0.38 feet	An ascension of no faster than 0.25 feet per week	Protect within basin and downstream habitat and wildlife.
WCA-3A NE	Stage increased by 0.18 feet	An ascension of no faster than 0.25 feet per week	Conserve water, maintain within basin and downstream habitat and wildlife. Provide suitable depths for aquatic prey and protect against peat soil loss during the dry season.
WCA-3A NW	Stage decreased by 0.03 feet	An ascension of no faster than 0.25 feet per week	
Central WCA-3A S	Stage increased by 0.20 feet	An ascension of no faster than 0.25 feet per week	Conserve water, maintain within basin and downstream habitat and wildlife. Provide suitable depths for aquatic prey and protect against peat soil loss during the dry season.
Southern WCA-3A S	Stage increased by 0.04 feet		
WCA-3B	Stage increased by 0.01 feet	An ascension of no faster than 0.25 feet per week	Protect within basin and downstream habitat and wildlife.
ENP-SRS	Stage increased by 0.05 feet	Make discharges to ENP according to COP protocol, considering up/down stream ecological conditions	Protect within basin and upstream habitat and wildlife.
Taylor Slough	Stage changes ranged from -0.23 feet to +0.10 feet	Move water southward as possible	When available, provide freshwater to promote water movement.
FB- Salinity	Salinity changes ranged from -2.9 to +9.6	Move water southward as possible	When available, provide freshwater to promote water movement.
